

Lab Instructions - session 5

Reading from camera device, edge detection

Part 1. Reading from a webcam

The following code reads a video stream from a webcam and displays it.

File: read_webcam.py

```
import numpy as np
import cv2
cam id = 0 # camera id
# for default webcam, cam id is usually 0
# try out other numbers (1,2,..) if this does not work
# If you are on linux, you can use the command
 " ls /dev/video* " to see available webcams.
cap = cv2.VideoCapture(cam id)
while True:
   ret, I = cap.read();
   cv2.imshow("my stream", I);
   # press "q" to quit
   if cv2.waitKey(1) & 0xFF == ord('q'):
       break
cap.release()
cv2.destroyAllWindows()
```

Part 2. Edge detection

Computing the Gradients

We compute Sobel gradients both by applying a Sobel filter and by using the OpenCV function "Sobel".

File: sobel1.py

```
import numpy as np
import cv2
from matplotlib import pyplot as plt
I = cv2.imread("agha-bozorg.jpg", cv2.IMREAD GRAYSCALE)
# Compute the gradient in x direction using the sobel filter
# Method 1: using filter2D *******
Dx = np.array([[-1, 0, 1],
               [-2, 0, 2],
               [-1, 0, 1]]); # Sobel filter
Ix = cv2.filter2D(I, -1, Dx);
print(I.dtype)
print(Ix.dtype)
Ix = cv2.filter2D(I, cv2.CV 16S, Dx); # cv2.CV 16S: 16 bit signed integer
print(Ix.dtype)
input('press ENTER to continue...')
# Method 2: using sobel function ********
Ix2 = cv2.Sobel(I,cv2.CV 16S,1,0)
print(np.abs(Ix - Ix2).max())
input('press ENTER to continue...')
# Plot the gradient image
f, axes = plt.subplots(2, 2)
axes[0,0].imshow(I,cmap = 'gray')
axes[0,0].set title("Original Image")
axes[0,1].imshow(Ix,cmap = 'gray')
axes[0,1].set_title("Ix (cv2.filter2D)")
axes[1,0].imshow(Ix2,cmap = 'gray')
axes[1,0].set title("Ix2 (cv2.Sobel)")
axes[1,1].imshow(np.abs(Ix),cmap = 'gray')
axes[1,1].set title("abs(Ix)")
# Notice that imshow in matplotlib considers the minimums value of I
# as black and the maximum value as white (this is different from
# the behavior in cv2.imshow
plt.show()
```

- Why have we used cv2.cv_16s (16 bit signed integer) format for the output of filter2D and Sobel functions, instead of -1 (which gives the same numeric type as the input image, i.e. CV_8U or unsigned 8-bit integer)?
- What is the value of np.abs(Ix Ix2).max()? Are Ix and Ix2 different?
- Why are most of the pixels in images of axes[0,1] and axes[1,0] gray?
 What do the black and white pixels show in these images? (notice that matplotlib automatically sets the minimum value of an image to black and the maximum value to white)

Towards edge detection!

The strength of the edge at each certain pixel can be represented by the magnitude of the gradient vector, that is

$$\sqrt{(\partial I/\partial x)^2 + (\partial I/\partial y)^2}$$

The next code plots the gradient in x and y directions, plus the magnitude of the gradient.

File: sobel2.py

```
import numpy as np
import cv2
from matplotlib import pyplot as plt
I = cv2.imread("agha-bozorg.jpg", cv2.IMREAD GRAYSCALE)
# Sobel gradient in the x direction
Ix = cv2.Sobel(I,cv2.CV 64F,1,0)
print(Ix.dtype)
# Sobel gradient in the y direction
Iy = cv2.Sobel(I,cv2.CV 64F,0,1)
print(Iy.dtype)
# Magnitude of gradient
E = np.sqrt(Ix*Ix + Iy*Iy)
# Plot the gradient image
f, axes = plt.subplots(2, 2)
axes[0,0].imshow(I,cmap = 'qray')
axes[0,0].set title("Original Image")
axes[0,1].imshow(abs(Ix),cmap = 'gray')
axes[0,1].set_title("abs(Ix)")
axes[1,0].imshow(abs(Iy),cmap = 'gray')
axes[1,0].set title("abs(Iy)")
axes[1,1].imshow(E,cmap = 'gray')
axes[1,1].set title("Magnitude of Gradient")
plt.show()
```

Edge detection (Sobel, Laplacian, Canny):

Now, we move on to edge detection. We use three different methods:

- 1. Using Sobel gradients + thresholding
- 2. Laplacian of Gaussian (LoG) + detection zero-crossings
- 3. Canny Edge detection

The function **zero_crossing** finds zero crossings in an image for LoG edge detection. You do not need to know how the functions **std_filter** and **zero_crossing** work.

File: edge.py

```
import numpy as np
import cv2
from matplotlib import pyplot as plt
def std filter(I, ksize):
   F = np.ones((ksize,ksize), dtype=np.float) / (ksize*ksize);
   MI = cv2.filter2D(I,-1,F) # apply mean filter on I
   I2 = I * I; # I squared
   MI2 = cv2.filter2D(I2,-1,F) # apply mean filter on I2
   return np.sqrt(abs(MI2 - MI * MI))
def zero crossing(I):
   """Finds locations at which zero-crossing occurs, used for
   Laplacian edge detector"""
   Ishrx = I.copy();
   Ishrx[:,1:] = Ishrx[:,:-1]
   Ishdy = I.copy();
   Ishdy[1:,:] = Ishdy[:-1,:]
    ZC = (I==0) \mid (I * Ishrx < 0) \mid (I * Ishdy < 0); # zero crossing
locations
   SI = std filter(I, 3) / I.max()
   Mask = ZC & (SI > .1)
   E = Mask.astype(np.uint8) * 255 # the edges
   return E
I = cv2.imread("agha-bozorg.jpg", cv2.IMREAD GRAYSCALE)
# set the sigma for Gaussian Blurring
sigma = 7
# Sobel magnitude of gradient
thresh = 90 # threshold
```

```
Ib = cv2.GaussianBlur(I, (sigma, sigma), 0); # blur the image
Ix = cv2.Sobel(Ib,cv2.CV_64F,1,0)
Iy = cv2.Sobel(Ib,cv2.CV 64F,0,1)
Es = np.sqrt(Ix*Ix + Iy*Iy)
Es = np.uint8(Es > thresh) *255 # threshold the gradients
# Laplacian of Gaussian
# Here, we first apply a Gaussian filter and then apply
# the Laplacian operator (instead of applying the LoG filter)
Ib = cv2.GaussianBlur(I, (sigma, sigma), 0);
E1 = cv2.Laplacian(Ib,cv2.CV 64F,ksize=5)
El = zero crossing(El);
# Canny Edge detector
1th = 50  # low threshold
hth = 120 # high threshold
Ib = cv2.GaussianBlur(I, (sigma, sigma), 0); # blur the image
Ec = cv2.Canny(Ib, lth, hth)
f, axes = plt.subplots(2, 2)
axes[0,0].imshow(I,cmap = 'gray')
axes[0,0].set title("Original Image")
axes[0,1].imshow(Es,cmap = 'gray')
axes[0,1].set title("Sobel")
axes[1,0].imshow(El,cmap = 'gray')
axes[1,0].set title("Laplacian")
axes[1,1].imshow(Ec,cmap = 'gray')
axes[1,1].set title("Canny")
# Notice that imshow in matplotlib considers the minimums value of I
# as black and the maximum value as white (this is different from
# the behavior in cv2.imshow)
plt.show()
```

- Compare the Canny edge detector to Sobel+thresholding. Can you see the effect of non-maximum suppression?
- Notice that in all cases we first smooth the image using a Gaussian filter.
 What is the purpose of smoothing the image? Change the smoothing
 parameter sigma (from sigma=7 to sigma=5, 3, 1 or 9) and see what
 happens by increasing or decreasing this parameter.
- Change the low and high thresholds of the Canny edge detector and observe the results.

Today's task:

You need to read a video stream from your webcam and apply different gradients or edge detection operations to the stream. You have to do this by completing the file **lab5_task1.py.** Your program must have the following functionalities:

- press the 'o' key: show the original webcam frame (already done)
- **press the 'x' key:** show the Sobel gradient in the x direction (already done)
- press the 'y' key: show the Sobel gradient in the y direction
- press the 'm' key: show the Sobel magnitude of the gradient
- press the 's' key: show the result of Sobel + thresholding edge detection
- press the 'I' key: apply Laplacian of Gaussian (LoG) edge detector
- press the 'c' key: apply Canny edge detector
- press the '+' key: increase smoothing parameter sigma (already done)
- press the '-' key: decrease smoothing parameter sigma (already done)
- press the 'q' key: quit the program (already done)

Notice that after reading each image frame we apply a Gaussian filter to blur it. All gradient/edge detection operations must be done on the blurred image Ib.

File: lab5 task1.py

```
import numpy as np
import cv2
cam id = 0 # camera id
# for default webcam, cam_id is usually 0
# try out other numbers (1,2,..) if this does not work
cap = cv2.VideoCapture(cam id)
mode = 'o' # show the original image at the beginning
sigma = 5
while True:
   ret, I = cap.read();
   #I = cv2.imread("agha-bozorg.jpg") # can use this for testing
    I = cv2.cvtColor(I, cv2.COLOR BGR2GRAY) # convert to grayscale
    Ib = cv2.GaussianBlur(I, (sigma, sigma), 0); # blur the image
    if mode == 'o':
        # J = the original image
        J = I
    elif mode == 'x':
        # J = Sobel gradient in x direction
        J = np.abs(cv2.Sobel(Ib,cv2.CV 64F,1,0));
```

```
elif mode == 'v':
        # J = Sobel gradient in y direction
   elif mode == 'm':
       # J = magnitude of Sobel gradient
   elif mode == 's':
        # J = Sobel + thresholding edge detection
       pass
   elif mode == '1':
       # J = Laplacian edges
       pass
   elif mode == 'c':
        # J = Canny edges
       pass
   # we set the image type to float and the maximum value to 1
   # (for a better illustration) notice that imshow in opency does not
   # automatically map the min and max values to black and white.
   J = J.astype(np.float) / J.max();
   cv2.imshow("my stream", J);
   key = chr(cv2.waitKey(1) & 0xFF)
   if key in ['o', 'x', 'y', 'm', 's', 'c', 'l']:
       mode = key
   if key == '-' and sigma > 1:
       sigma -= 2
       print("sigma = %d"%sigma)
   if key in ['+','=']:
       sigma += 2
       print("sigma = %d"%sigma)
   elif key == 'q':
       break
cap.release()
cv2.destroyAllWindows()
```

- Wave your hand quickly. What happens to the edges? Why?
- Press the 's' and 'c' keys to compare **Canny** with **Sobel** edge detection. Explain the effect of non-maximum suppression to the TA.
- In each case, increase and decrease the **sigma** by pressing + and keys and see what happens. Explain the reason to the TA.
- Ideally, you can also use cv2.putText() function to label your images so that you can compare them easily.
